

MP23701

24V, 2A, 1.5MHz, Synchronous,
Step-Down LED Driver

DESCRIPTION

The MP23701 is a 24V, monolithic, synchronous, step-down, white LED driver with a built-in power MOSFET and rectifier. The MP23701 can achieve up to 2A of continuous output current with excellent load and line regulation. Peak-current mode operation provides fast transient response and easy loop stabilization.

The MP23701 implements deep analog dimming. Full protection features include cycle-by-cycle peak-current limiting, output short-circuit protection (SCP), open LED protection, NTC thermal protection, and thermal shutdown.

The MP23701 requires a minimal number of readily available, standard, external components and is available in a UTQFN-8 (1.5mmx2.5mm) package.

FEATURES

- 4.2V to 24V Wide Input Range
- Synchronous Step-Down Converter
- 100mΩ Internal High-Side Power MOSFET
- 80mΩ Internal Low-Side Synchronous Rectifier
- Peak-Current Mode Control
- Up to 2A Continuous Output Current
- 100mV Feedback Voltage
- Up to 97% Efficiency
- Fixed 1.5MHz Switching Frequency
- Analog Dimming
- Cycle-by-Cycle Current Limit
- Inherent LED Open Protection
- Output Short-Circuit Protection (SCP)
- NTC Thermal Protection
- Thermal Shutdown
- Auto-Restart Function
- Available in a UTQFN-8 (1.5mmx2.5mm) Packages

APPLICATIONS

- Infrared LED Drivers
- General LED Drivers
- Flashlights
- Handheld Computer Backlight

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS", the MPS logo, and "Simple, Easy Solutions" are trademarks of Monolithic Power Systems, Inc. or its subsidiaries.

TYPICAL APPLICATION

Efficiency vs. V_{IN}

$V_{IN}=12V$, 2 WLEDs in series, $V_{OUT}=5.9V$,
 $T_A = 25^\circ C$

PACKAGE REFERENCE

PIN FUNCTIONS

Pin #	Name	Description
1	NC	No connection.
2	VIN	Supply voltage. The MP23701 operates on a 4.2V to 24V unregulated input range. An input capacitor is needed to prevent large voltage spikes from appearing at the input.
3	SW	Switch output.
4	GND	Ground. GND is the voltage reference for the regulated output voltage. Pay careful attention to GND during layout.
5	BST	Bootstrap. Connect a capacitor between SW and BST to form a floating supply across the power switch driver. This capacitor is needed to drive the power switch's gate above the supply voltage.
6	EN/DIM	On/off control input and dimming command input. Leave EN/DIM floating or apply a voltage higher than 0.59V on EN/DIM to turn on the MP23701. For analog dimming, when the EN/DIM voltage rises up from 0.7V to 1.44V, the output current changes from its minimum value to the full-scale LED current.
7	FB	Current sense feedback voltage. The FB internal reference voltage is 0.1V.
8	NTC	LED temperature protection. Connect an NTC resistor from NTC to GND to reduce the output current to protect the LED when the ambient temperature rises up at high levels.

ABSOLUTE MAXIMUM RATINGS ⁽¹⁾

Supply voltage (V_{IN})26V
 V_{SW} -0.3V to $V_{IN} + 0.3V$
 V_{BST} $V_{SW} + 6V$
 All other pins..... -0.3V to +6V
 Continuous power dissipation ($T_A = 25^\circ C$) ⁽²⁾
 UTQFN-8 (1.5mm x 2.5mm) 1.39W
 Junction temperature 150°C
 Lead temperature 260°C
 Storage temperature -65°C to +150°C
 ESD capability human body mode 2.0kV

Recommended Operating Conditions ⁽³⁾

Supply voltage (V_{IN}) 4.2V to 24V
 Operating junction temp. (T_J) -40°C to 125°C

Thermal Resistance ⁽⁴⁾

θ_{JA} θ_{JC}
 UTQFN-8 (1.5mmx2.5mm)..... 90 20 ... °C/W

NOTES:

- 1) Exceeding these ratings may damage the device.
- 2) The maximum allowable power dissipation is a function of the maximum junction temperature T_J (MAX), the junction-to-ambient thermal resistance θ_{JA} , and the ambient temperature T_A . The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = $(T_J$ (MAX) - T_A) / θ_{JA} . Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- 3) The device is not guaranteed to function outside of its operating conditions.
- 4) Measured on JESD51-7, 4-layer PCB.

ELECTRICAL CHARACTERISTICS

Typical values are $V_{IN} = 12V$, $T_J = 25^{\circ}C$, unless otherwise noted. Minimum and maximum values are at $V_{IN} = 12V$, $T_J = -40^{\circ}C$ to $+125^{\circ}C$, unless otherwise noted, guaranteed by characterization.

Parameters	Symbol	Condition	Min	Typ	Max	Units
Supply Voltage						
Operating range	V_{IN}	After turn on	4.2		24	V

BLOCK DIAGRAM

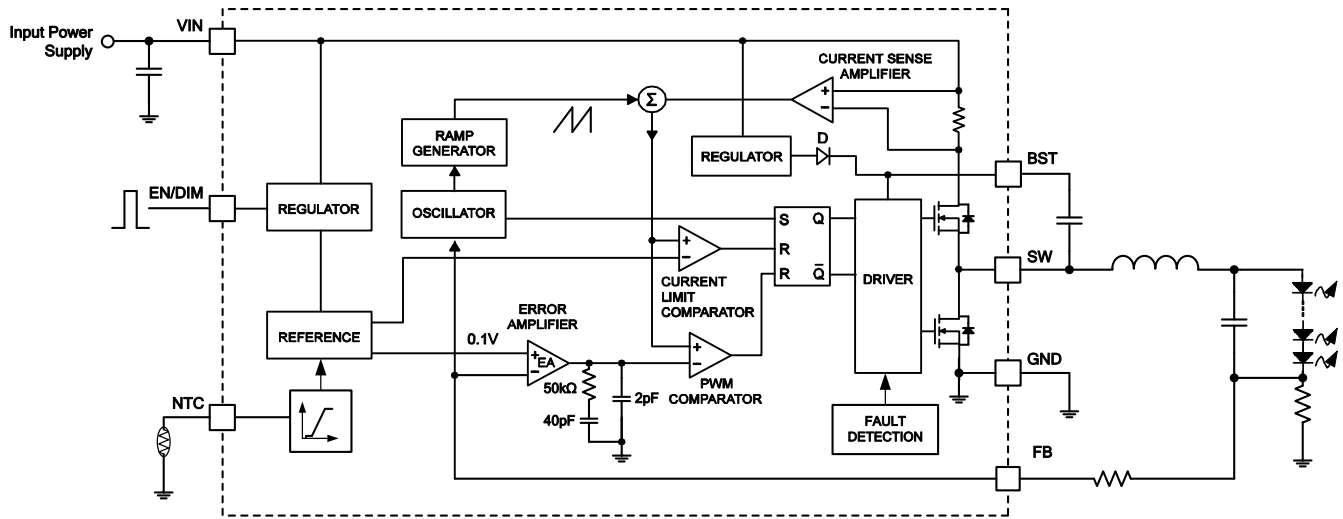

Figure 1: Functional Block Diagram

OPERATION

The MP23701 is a high-frequency, synchronous, rectified, step-down, switch-mode LED driver with a built-in, internal power MOSFET and synchronous rectifier switch. The MP23701 offers a very high-performance solution that achieves up to 2A of continuous output LED current with excellent load and line regulation over a wide input supply range.

The MP23701 operates with a fixed 1.5MHz frequency and uses peak-current control mode to regulate the output current. A new switching cycle is initiated by the internal clock at the beginning of every switching cycle.

The integrated high-side power MOSFET (HS-FET) is turned on, and the inductor current rises linearly to provide energy to the load. The HS-FET remains on until its current reaches the value of the COMP level, which is the output of the internal error amplifier. The output voltage of the error amplifier depends on the difference of the output feedback and the internal, high-precision reference.

The HS-FET remains off until the next clock cycle begins. After the HS-FET turns off, the low-side sync switch (LS-FET) turns on, and the inductor current flows through the LS-FET. To prevent shoot-through, a dead time is implemented to prevent the HS-FET and LS-FET from turning on at the same time.

If the duty cycle reaches 94% in one switching period, the current in the HS-FET cannot reach the COMP-set current value, and the HS-FET is forced to turn off.

Under-Voltage Lockout (UVLO) and IC Start-Up/Shutdown Procedure

Under-voltage lockout (UVLO) is implemented to prevent the chip from operating at an insufficient supply voltage. The MP23701 UVLO comparator monitors the output voltage of the internal regulator, which is supplied from V_{IN} .

If both V_{IN} and EN/DIM are higher than their appropriate thresholds, the chip starts up. The reference block starts first to generate a stable reference voltage and current. The internal regulator is then enabled. The regulator provides a stable supply for the remaining circuitries.

Three events can shut down the chip: EN/DIM dropping low for longer than t_{OFF_DELAY} , V_{IN} dropping below UVLO, and thermal shutdown. During the shutdown procedure, the signaling path is blocked first to prevent any fault triggering. The COMP voltage (V_{COMP}) and the internal supply rail are then pulled down.

Error Amplifier (EA)

The internal, low, offset error amplifier compares the FB voltage with the internal 100mV reference and outputs a V_{COMP} value in the chip internally. This V_{COMP} value is used to control the HS-FET peak current and regulate the output current.

Internal Soft Start (SS)

Soft start (SS) is implemented to prevent the converter output current from overshooting during start-up. When the chip starts up, the internal circuitry generates a soft-start voltage that ramps up from 0V. The soft-start period lasts until the voltage on the soft-start capacitor exceeds the 0.1V reference voltage. At this point, the reference voltage takes over.

Floating Driver and Bootstrap Charging

The high-side, floating, power MOSFET driver is powered by an external bootstrap capacitor. The bootstrap capacitor voltage is regulated internally. During normal operation, a 5.1V bootstrap voltage is maintained between BST and SW.

Enable and Dimming Control (EN/DIM)

EN/DIM is a control pin that turns the regulator on and off and dims the output LED current through a DC signal. Leave EN/DIM floating or drive it high to turn on the MP23701. After EN/DIM is pulled low for t_{OFF_DELAY} (typically 22ms), the MP23701 is turned off. Figure 2 shows the control logic of EN/DIM.

Figure 2: EN/DIM Time Sequence

Analog Dimming

Apply a DC signal on EN/DIM to dim the MP23701 in analog dimming mode. When the voltage on EN/DIM is lower than V_{ADIM_MIN} , the LED current is regulated to the minimum scale. When the voltage on EN/DIM is between V_{ADIM_MIN} and V_{ADIM_MAX} , the LED current changes from the minimum scale to the full scale of the LED current. If the voltage on EN/DIM is higher than V_{ADIM_MAX} , the maximum LED current is regulated.

Figure 3 shows the analog dimming curve. Due to the hysteric of the EN/DIM on/off threshold, the chip remains at the minimal LED current longer at the $V_{EN/DIM}$ falling edge until $V_{EN/DIM}$ is lower than V_{EN_OFF} . The dimming curve is the same as in the linear dimming range.

Figure 3: Analog Dimming Curve

Open LED

If the LED is open without a feedback signal, the MP23701 works at the maximum duty cycle, and the output voltage rises up almost to the input voltage. Every power component operates at a safe state.

LED Short-Circuit Protection (SCP)

The MP23701 integrates LED short-circuit protection (SCP) circuitry. There are several features protecting the MP23701 from damage when an LED short circuit occurs.

The MP23701 uses a cycle-by-cycle current limit to restrict the maximum current of the inductor. A protection mechanism monitors the FB level through an internal R-C filter. Once the FB level rises up to $V_{FB_BURST_AL}$, the chip stops switching until the FB level drops to a lower value, and the system works in burst mode.

In the worst-case scenario, the LED is shorted to GND. If the cycle-by-cycle current-limit function cannot clamp the current overshoot sufficiently, then the current through both the HS-FET and LS-FET is also monitored by the over-current detector inside the chip. If this current is higher than the short-circuit threshold (I_{OCP}), the MP23701 treats this as a short-circuit condition.

When an over-current condition or short-circuit condition is detected, the MP23701 turns off both the HS-FET and LS-FET for 2.4ms and restarts. During this period, V_{COMP} is pulled down to ground, so the restart from the fault condition is also done with a soft start.

Thermal Protection

NTC provides LED thermal protection. An NTC resistor used to monitor the ambient temperature can be connected to NTC directly. There is an internal current source flowing out of NTC. The corresponding voltage is generated on the external NTC resistor and the LED current changes (see Figure 4).

Figure 4: NTC Curve

The NTC resistance value drops when the ambient temperature rises up. If the NTC voltage drops below V_{SD_NTC} , the switching stops completely, and the LED current drops to 0A, so the LED lamp can be shut down by pulling NTC down.

Additionally, to protect against any lethal thermal damage, when the inner temperature exceeds the over-temperature protection (OTP) threshold, the MP23701 uses thermal shutdown to shut down the switching cycle until the temperature drops to its lower threshold.

Thermal Shutdown

Thermal shutdown is implemented to prevent the chip from operating at exceedingly high temperatures. When the silicon die temperature is higher than 150°C, OTP shuts down the entire chip. When the temperature is below its lower threshold (typically 90°C), the chip restarts.

APPLICATION INFORMATION

Setting the LED Current

A current sense resistor is inserted between the anode of LED and GND. The current sense resistor value can be calculated with Equation (1):

$$R_S = \frac{0.1V}{I_{LED}} \quad (1)$$

For a 2A LED current output, R_S is 50mΩ.

Selecting the Inductor

An inductor less than 100μH with a nominal DC current rating at least 25% higher than the maximum load current is recommended for most applications. For the highest efficiency, the inductor's DC resistance should be less than 100mΩ. For most designs, the required inductance value can be derived from Equation (2):

$$L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times \Delta I_L \times f_{SW}} \quad (2)$$

Where ΔI_L is the inductor ripple current.

Choose the inductor ripple current to be 30% of the maximum load current. The maximum inductor peak current can be calculated with Equation (3):

$$I_{L(MAX)} = I_{LED} + \frac{\Delta I_L}{2} \quad (3)$$

Selecting the Input Capacitor

The input capacitor reduces the surge current drawn from the input supply and the switching noise from the device. The input capacitor impedance at the switching frequency should be less than the source impedance to prevent the high-frequency switching current from passing through the input. Ceramic capacitors with X5R or X7R dielectrics are highly recommended because of their low ESR and small temperature coefficients. For most applications, a 10μF capacitor is sufficient.

Selecting the Output Capacitor

The output capacitor keeps the output current ripple small and ensures feedback loop stability. The output capacitor impedance should be low at the switching frequency. Ceramic capacitors with X5R or X7R dielectrics are recommended for their low ESR characteristics. For most applications, a 10μF ceramic capacitor is sufficient.

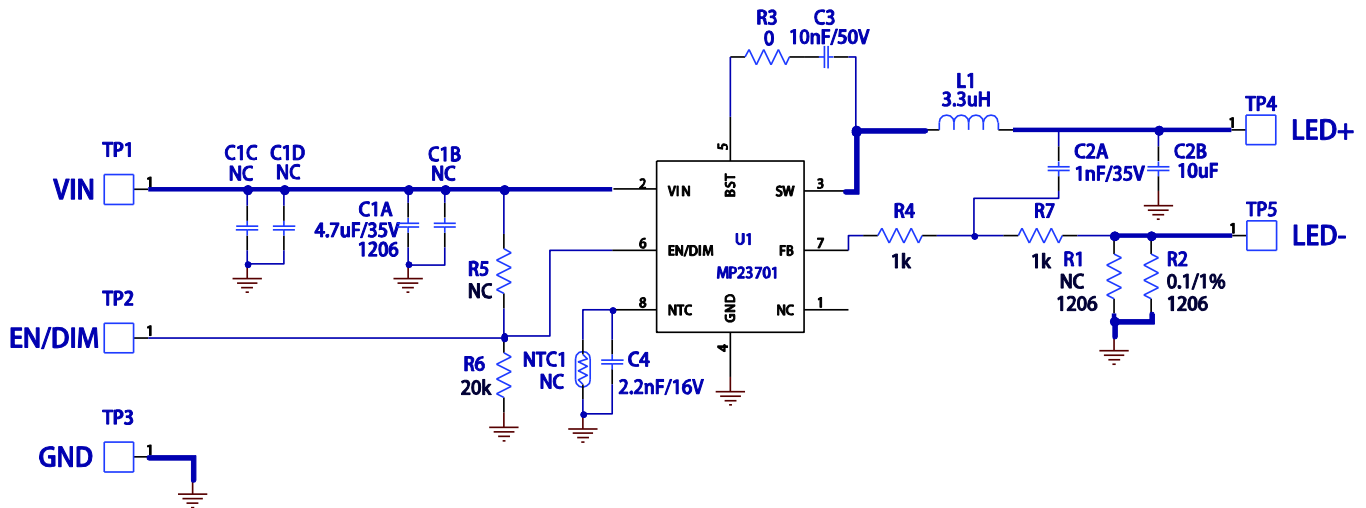

PCB Layout Guidelines

Efficient PCB layout is critical for stable operation. For best results, follow the guidelines below.

1. Place the high-current paths (GND, VIN, and SW) very close to the device with short, direct, and wide traces.
2. Place the input capacitor as close to VIN and GND as possible.
3. Place the external feedback resistors next to FB.
4. Keep the switch node traces short and away from the feedback network.

For more information, please refer to the related evaluation board datasheet.
